Adventure Works: The ultimate source for outdoor equipment

Original Design:

For every permutation:

1. Read every line of a text file dictionary
2. Compare with the current permutation
3. Print it if it was a match

Permutations: $n!$

Permutations * 235969 = number of comparisons

Big-Theta of $n!$

Next Design: Hash Table with chaining

- Decide average linked list iteration: 8
 - Make 8 comparisons on average to see if a permutation matches anything in the dictionary
- Searching time for one permutation: $\theta(8) = \theta(1)$
- Searching time for all permutations: $\theta(1) * \theta(n!) = \theta(n!)$
- Big-Theta is the same, but its much faster than previous because we do not have to compare 235,969 words. We only compare 8 on average.

Hash Table with chaining

- $235,969 \text{ words} / 8 \text{ average linked list} = 29,495.125$
- Closest power of 2 = 32,768
- Closest prime number = 29,501
- Size of table = 29,501
- Actual average searching time: $235,969 / 29,501 = 7.998$ comparisons

Initialization

- Create dictionary array of linked list with the size of the dictionary
- Read text file with dictionary words
- The word is the key
 - Hash the key
 - Insert into array at the end of the linked list

Choosing Good Hash Function

1. Large enough to achieve highest index location (29,500)
2. Variety in operations
Need more than just add and subtract
3. Use as many variables as possible
Using constants will result in the same values for the same letters

```
int hashh(string key)
{
    int index = 1;
    for (int i = 0; i < key.length(); i++)
        index += (key.at(i))*(i + 65) + (key.at(i)%(i+1));

    index = abs(index);    // its negative if overflowed
    return index %= dSize; // index mod dSize
}
```

personality

All words with letters "personality" will now be listed!
personality,

There were 1 matching words :)

Average Linked List: 5.29178
Timer took 673.179s
```

- 11 Letter words
- Takes a looong time

Improvements

- Reduce average searching time from 8 to 4 or something.
 - Uses more memory
- Alphabetized Linked List?
 - If the key is less than the head of the linked list then do not check the rest of the list
- Check `key.length()`?
 - If the length of the key does not equal the word then do not compare the individual letters.
- Always have $n!$ permutations of the letters $\rightarrow \theta(n!)$

Thank you

Riley Tallman
